

# Recursion

Instructor: Chi Tse (Ricky)

Slides adopted from professor Kent Chin and professor Jean Lai

# What is Recursion?

- **Recursion:**

A function calling itself to solve a simpler form of the same problem.

- **Recursive Function:**

Base Case – terminate case

Iterative Step – What the function should do in each step

# Example 1: Factorial

Recursive algorithms work as follows:

When your problem is small and easy (i.e. cannot be broken down), just return the answer! We call this the **base case** (it's possible to have more than one base case).

If your problem is too difficult, solve a smaller problem! This is where we make one or more *recursive* calls.

```
int factorial(int x) {  
    if (x <= 1) return 1; //base case, 0! = 1! = 1  
    return x * factorial(x-1); //recursive call
```

$$x! = x * (x-1) * \dots * 5 * 4 * 3 * 2 * 1$$

Smaller problem:  $(x-1)!$

# Trace

↑ **24**  
*factorial*(4);  
4 ≤ 1 → *false*  
return 4 \* *factorial*(x-1)

↓ ↑ **6**  
*factorial*(3);  
3 ≤ 1 → *false*  
return 3 \* *factorial*(x-1)

↓ ↑ **2**  
*factorial*(2);  
2 ≤ 1 → *false*  
return 2 \* *factorial*(x-1)

↓ ↑ **1**  
*factorial*(1);  
1 ≤ 1 → *true*, so return 1

## Notes

- Red arrows represent function calls.
- Orange arrows represent values being returned

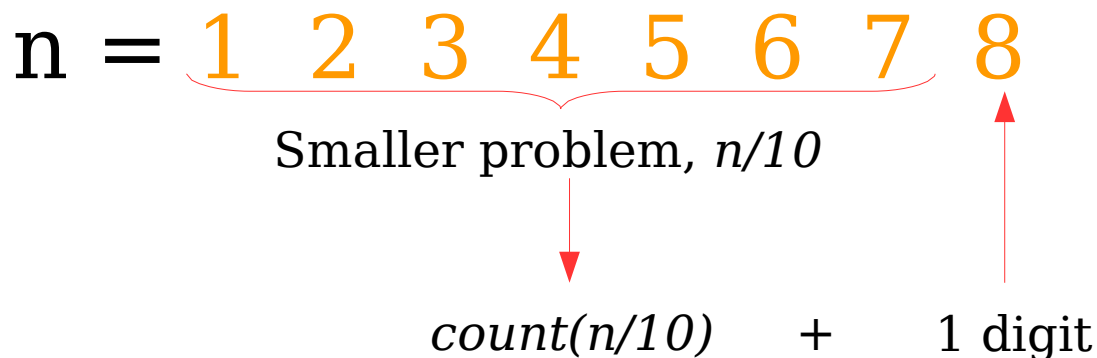

# Example 2: Counting Digits

Function Prototype: `int count(int n);`

Base Case: A single digit number has 1 digit, so if  $n < 10$ , return 1

Recursive Case: **1 + # of digits in the rest of n**

```
int count(int n) {  
    if (n < 10) return 1;  
    return count(n/10) + 1;  
}
```

*12345678 is just a dummy number being used for illustration.*

# Trace

↑ **4**  
*count*(1234);  
1234 < 10 → *false*  
return *count*(n/10) + 1

↓ ↑ **3**

*count*(123);  
123 < 10 → *false*  
return *count*(n/10) + 1

↓ ↑ **2**

*count*(12);  
12 < 10 → *false*  
return *count*(n/10) + 1

↓ ↑ **1**

*count*(1);  
1 < 10 → *true*, so return 1

## Notes

- **Red** arrows represent function calls
- **Orange** arrows represent values being returned.

# Example 3: Summing Digits

Function Prototype: `int sum_digits(int n);`

Base Case: If single digit's sum is itself, so if  $n < 10$ , return  $n$ .

Recursive Case: ***last digit + sum of rest of the digits of n***

```
int sum_digits(int n) {  
    if (n < 10) return n;  
    return sum_digits(n/10) + (n%10);  
}
```

$n = 1\ 2\ 3\ 4\ 5\ 6\ 7\ 8$

Smaller problem,  $n/10$

$sum\_digits(n/10) +$  Last digit

*12345678 is just a dummy number being used for illustration.*

# Trace

↑ **30**  
*sum\_digits*(6789);  
6789 < 10 → *false*  
return *sum\_digits*(n/10) + 9

↓ ↑ **21**  
*sum\_digits*(678);  
678 < 10 → *false*  
return *sum\_digits*(n/10) + 8

↓ ↑ **13**  
*sum\_digits*(67);  
67 < 10 → *false*  
return *sum\_digits*(n/10) + 7

↓ ↑ **6**  
*sum\_digits*(6);  
6 < 10 → *true*, so return 6

## Notes

- Red arrows represent function calls.
- Orange arrows represent values being returned

# Example 4: Doubling All Digits

```
cout << double_digits(1) << endl;    //11
cout << double_digits(21) << endl;   //2211
cout << double_digits(101) << endl;  //110011
```

Function Prototype: `int double_digits(int n);`

Base Case: If  $n < 10$ , return  $n*11$  (this “doubles” a single digit).

Recursive Case: ***the last digit doubled + (the rest of the digits doubled)\*100*** (to make “room” for the doubled last digit)

```
int double_digits(int n)
    if (n < 10) return n*11;
    return double_digits(n/10)*100 + (n%10)*11;
```

$n = 1\ 2\ 3\ 4\ 5\ 6\ 7\ 8$

Smaller problem,  $n/10$

*12345678 is just a dummy number being used for illustration.*

# Example 5: Summing Odd Digits, only

```
cout << sum_odd(123) << endl; //4
cout << sum_odd(211) << endl; //2
```

Function Prototype: `int sum_odd(int n);`

Base Case: If  $n == 0$ , the sum is 0, so return 0.

Recursive Cases:

- If last digit is odd, add the last digit with the sum of the *rest of the odd digits of n* (recursive call!).
- Otherwise, just return the sum of the *rest of the odd digits of n* (recursive call!).

```
int sum_odd(int n) {
    if (n == 0) return 0;
    if (n % 2 == 1) //same as (n%10) % 2 == 1
        return sum_odd(n/10) + (n%10);
    else
        return sum_odd(n/10);
}
```

# Example 6: Fibonacci

```
int Fibonacci (int n)
{
    if (n <= 1)
        return n;
    else
        return Fibonacci(n-1) + Fibonacci(n-2);
}
```

**Base case**  
*No recursion calls!*

return Fibonacci(n-1) + Fibonacci(n-2);

**Smaller problem**  
*with smaller input size.*

# Example 6: Fibonacci
